# 1 Introduction

Given the opportunity to review the design document and related smart contract source code of the MORE Markets protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

#### 1.1 About MORE Markets

MORE Markets protocol is a decentralized protocol for lending and borrowing. It is designed to provide safe and efficient foundation for lending markets with competitive fees and reliable price discovery. The initial release of the protocol is based on a fork of Aave v3.0 without any modifications. However, Chainlink oracles are replaced by Pyth and custom oracles wrapped as Pyth oracles for price feeds, aggregating data from both decentralized and centralized exchanges to ensure accurate pricing. Liquidity providers earn fees based on the performance of their deposits and utilization rates from borrowing activity. Borrowers benefit from access to flexible, low-cost liquidity. The basic information of the audited protocol is as follows:

Table 1.1: Basic Information of MORE Markets

Item Description

#### 1.2 About PeckShield

PeckShield Inc. [9] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

### 1.3 Methodology

To standardize the evaluation, we define the following terminology based on the OWASP Risk Rating Methodology [8]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a checklist of items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [7], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

Table 1.3: The Full Audit Checklist

Category	Checklist Items

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during
	the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functional-
	ity that processes data.
Numeric Errors	Weaknesses in this category are related to improper calcula-
	tion or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like
	authentication, access control, confidentiality, cryptography,
	and privilege management. (Software security is not security
	software.)
Time and State	Weaknesses in this category are related to the improper man-
	agement of time and state in an environment that supports
	simultaneous or near-simultaneous computation by multiple
Funcio Con divisione	systems, processes, or threads.
Error Conditions,	Weaknesses in this category include weaknesses that occur if
Return Values, Status Codes	a function does not generate the correct return/status code, or if the application does not handle all possible return/status
Status Codes	codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper manage-
Resource Management	ment of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behav-
Deliavioral issues	iors from code that an application uses.
Business Logic	Weaknesses in this category identify some of the underlying
Dusiness Togic	problems that commonly allow attackers to manipulate the
	business logic of an application. Errors in business logic can
	be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used
	for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of
	arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written
	expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices
	that are deemed unsafe and increase the chances that an ex-
	ploitable vulnerability will be present in the application. They
	may not directly introduce a vulnerability, but indicate the
	product has not been carefully developed or maintained.

#### 1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

# 2 | Findings

### 2.1 Summary

Here is a summary of our findings after analyzing the implementation of the MORE Markets protocol. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings
Critical	0
High	0
Medium	1
Low	2
Informational	1
Total	4

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

### 2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability, 2 low-severity vulnerabilities, and 1 informational recommendation.

ID **Title** Severity Category **Status** PVE-001 Timely Rate Adjustment Upon Pool In-Low Business Logic Resolved terest Rate Strategy Change **PVE-002** Improved Asset Addition Logic in Con-Low Business Logic Resolved figuratorLogic PVE-003 Informational Suggested Immutable Storage State Coding Practices Resolved When Assigned Only in Constructor **PVE-004** Medium Trust Issue of Admin Keys Mitigated Security Features

Table 2.1: Key MORE Markets Audit Findings

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

# 3 Detailed Results

# 3.1 Timely Rate Adjustment Upon Pool Interest Rate Strategy Change

• ID: PVE-001

Severity: Low

• Likelihood: Low

Impact: Low

• Target: Pool

• Category: Business Logic [6]

• CWE subcategory: CWE-837 [3]

#### Description

The MORE Markets protocol allows the governance to dynamically configure the interest rate strategy for current reserves. The supported interest rate strategy implements the calculation of the interest rates depending on the reserve state. While reviewing current configuration logic, we notice the update of the interest rate strategy warrants the need of refreshing the latest stable borrow rate, the latest variable borrow rate, as well as the latest liquidity rate.

To elaborate, we show below the setReserveInterestRateStrategyAddress() function. It implements a rather straightforward logic in validating and applying the new interestRateStrategyAddress contract. It comes to our attention that the internal accounting for various rates is not timely refreshed to make it immediately effective. As a result, even if the interest rate strategy is already updated, current rates are not updated yet. In other words, the latest stable/variable borrow rate and the latest liquidity rate are still based on the replaced interest rate strategy.

```
535 }
```

Listing 3.1: Pool::setReserveInterestRateStrategyAddress()

**Recommendation** Revise the above logic to apply the give interestRateStrategyAddress for the give reserve.

Status The issue has been fixed by the following commit: ae73801.

### 3.2 Improved Asset Addition Logic in ConfiguratorLogic

• ID: PVE-002

Severity: LowLikelihood: Low

• Impact: Low

• Target: ConfiguratorLogic

• Category: Coding Practices [5]

• CWE subcategory: CWE-561 [2]

#### Description

The MORE Markets protocol has a core ConfiguratorLogic contract to allow for dynamic update of protocol parameters. In the process of examining the related setters, we notice one specific setter can be improved.

In particular, we show below the implementation of this related setter routine, i.e., executeInitReserve. As the name indicates, it is used to initialize a reserve by creating and initializing aToken, stable debt token, and variable debt token. It comes to our attention that the underlying token's decimals needs to be larger than ReserveConfiguration.DEBT\_CEILING\_DECIMALS.

```
50
     function executeInitReserve(
51
        IPool pool,
        ConfiguratorInputTypes.InitReserveInput calldata input
52
53
54
        address aTokenProxyAddress = _initTokenWithProxy(
55
          input.aTokenImpl,
56
          abi.encodeWithSelector(
57
            IInitializableAToken.initialize.selector,
58
            pool,
59
            input.treasury,
60
            input.underlyingAsset,
61
            input.incentivesController,
            input.underlyingAssetDecimals,
62
63
            input.aTokenName,
64
            input.aTokenSymbol,
65
            input.params
66
          )
```

```
68 ...
69 }
```

Listing 3.2: ConfiguratorLogic::executeInitReserve()

**Recommendation** Revise the above setter to ensure the given reserve's underlying asset meets the minimal decimals requirement.

Status The issue has been fixed by the following commit: 0bdc8a6.

### 3.3 Suggested Immutable States If Only Set at Constructor

• ID: PVE-003

• Severity: Informational

• Likelihood: N/A

• Impact: N/A

• Target: Multiple Contracts

• Category: Coding Practices [5]

• CWE subcategory: CWE-561 [2]

#### Description

Since version 0.6.5, Solidity introduces the feature of declaring a state as immutable. An immutable state variable can only be assigned during contract creation, but will remain constant throughout the life-time of a deployed contract. The main benefit of declaring a state as immutable is that reading the state is significantly cheaper than reading from regular storage, since it is not stored in storage anymore. Instead, an immutable state will be directly inserted into the runtime code.

This feature is introduced based on the observation that the reading and writing of storage-based contract states are gas-expensive. Therefore, it is always preferred if we can reduce, if not eliminate, storage reading and writing as much as possible. Those state variables that are written only once are candidates of immutable states under the condition that each fits the pattern, i.e., "a constant, once assigned in the constructor, is read-only during the subsequent operation."

While examining all the state variables defined in the AnkrFlowToUsdFeed contract, we observe there are several variables (e.g., ankrRatioFeed, ankrFlow, and flowFeed) that need not to be updated dynamically. They can be declared as immutable for gas efficiency. Note another contract PythAggregatorV3 can be similarly improved.

```
12 contract AnkrFlowToUsdFeed is AggregatorV2V3Interface {
13    IInternetBondRatioFeed public ankrRatioFeed;
14    address public ankrFlow;
15    AggregatorV2V3Interface public flowFeed;
16
17    constructor(address _ankrRatioFeed, address _ankrFlow, address _flowFeed) {
18    ankrRatioFeed = IInternetBondRatioFeed(_ankrRatioFeed);
```

```
19     ankrFlow = _ankrFlow;
20     flowFeed = AggregatorV2V3Interface(_flowFeed);
21   }
22     ...
24 }
```

Listing 3.3: Key Storage States Defined in AnkrFlowToUsdFeed

**Recommendation** Revisit the state variable definition and make good use of immutable/constant states.

Status The issue has been fixed by the following commit: 0bdc8a6.

### 3.4 Trust Issue of Admin Keys

• ID: PVE-004

• Severity: Medium

• Likelihood: Medium

Impact: Medium

• Target: Multiple Contracts

• Category: Security Features [4]

• CWE subcategory: CWE-287 [1]

#### Description

In the MORE Markets protocol, there are a few privileged admin accounts that play a critical role in governing and regulating the system-wide operations (e.g., parameter setting and marketing adjustment). It also has the privilege to control or govern the flow of assets managed by this protocol. Our analysis shows that the privileged account needs to be scrutinized. In the following, we examine the privileged account and their related privileged accesses in current contracts.

```
398
      function setUnbackedMintCap(
399
        address asset,
400
        uint256 newUnbackedMintCap
401
      ) external override onlyRiskOrPoolAdmins {
402
        DataTypes.ReserveConfigurationMap memory currentConfig = _pool.getConfiguration(
            asset);
403
        uint256 oldUnbackedMintCap = currentConfig.getUnbackedMintCap();
404
        currentConfig.setUnbackedMintCap(newUnbackedMintCap);
405
        _pool.setConfiguration(asset, currentConfig);
406
        emit UnbackedMintCapChanged(asset, oldUnbackedMintCap, newUnbackedMintCap);
407
      }
408
409
      /// @inheritdoc IPoolConfigurator
410
      function setReserveInterestRateStrategyAddress(
411
        address asset.
412
        address newRateStrategyAddress
```

```
413
      ) external override onlyRiskOrPoolAdmins {
414
         DataTypes.ReserveData memory reserve = _pool.getReserveData(asset);
415
         address oldRateStrategyAddress = reserve.interestRateStrategyAddress;
416
         _pool.setReserveInterestRateStrategyAddress(asset, newRateStrategyAddress);
417
         emit ReserveInterestRateStrategyChanged(asset, oldRateStrategyAddress,
             newRateStrategyAddress);
418
      }
419
420
      /// @inheritdoc IPoolConfigurator
      {\tt function} \ \ {\tt setPoolPause(bool\ paused)\ external\ override\ only Emergency Admin\ \{}
421
422
         address[] memory reserves = _pool.getReservesList();
423
424
        for (uint256 i = 0; i < reserves.length; i++) {</pre>
425
           if (reserves[i] != address(0)) {
426
             setReservePause(reserves[i], paused);
427
428
        }
429
      }
430
431
      /// @inheritdoc IPoolConfigurator
432
       function updateBridgeProtocolFee(uint256 newBridgeProtocolFee) external override
           onlyPoolAdmin {
433
434
           newBridgeProtocolFee <= PercentageMath.PERCENTAGE_FACTOR,</pre>
435
           Errors.BRIDGE_PROTOCOL_FEE_INVALID
436
437
         uint256 oldBridgeProtocolFee = _pool.BRIDGE_PROTOCOL_FEE();
438
         _pool.updateBridgeProtocolFee(newBridgeProtocolFee);
439
         emit BridgeProtocolFeeUpdated(oldBridgeProtocolFee, newBridgeProtocolFee);
440
```

Listing 3.4: Example Privileged Functions in the PoolConfigurator Contract

If these privileged admin accounts are managed by a plain EOA account, this may be worrisome and pose counter-party risk to the exchange users. A multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO. In the meantime, a timelock-based mechanism can also be considered as mitigation.

Moreover, it should be noted that current contracts have the support of being deployed behind a proxy. And there is a need to properly manage the proxy-admin privileges as they fall in this trust issue as well.

**Recommendation** Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been mitigated as the team has confirmed that these privileged functions

should be called by a trusted multi-sig account, not a plain EOA account.

# 4 Conclusion

In this audit, we have analyzed the design and implementation of the MORE Markets protocol, which is a decentralized protocol for lending and borrowing. It is designed to provide safe and efficient foundation for lending markets with competitive fees and reliable price discovery. The initial release of the protocol is based on a fork of Aave v3.0 without any modifications. However, Chainlink oracles are replaced by Pyth and custom oracles wrapped as Pyth oracles for price feeds, aggregating data from both decentralized and centralized exchanges to ensure accurate pricing. Liquidity providers earn fees based on the performance of their deposits and utilization rates from borrowing activity. Borrowers benefit from access to flexible, low-cost liquidity. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and fixed.

Moreover, we need to emphasize that Solidity-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
